1 Firewall Basic Syntax

Our firewall model supports the following actions.

```
 \begin{array}{l} \textbf{datatype} \ \ action = Accept \mid Drop \mid Log \mid Reject \mid Call \ string \mid Return \mid Empty \mid \\ Unknown \end{array}
```

The type parameter 'a denotes the primitive match condition For example, matching on source IP address or on protocol. We list the primitives to an algebra. Note that we do not have an Or expression.

 $\label{eq:datatype} \ \ 'a \ match-expr = Match \ \ 'a \ | \ MatchNot \ \ 'a \ match-expr \ | \ MatchAnd \ \ 'a \ match-expr \ | \ MatchAnd \ \ 'a$ $match-expr \ \ | \ MatchAny$

 ${f datatype-new}$ 'a rule=Rule (get-match: 'a match-expr) (get-action: action) ${f datatype-compat}$ rule

```

10 Boolean Matching vs. Ternary Matching

 $\begin{array}{l} \textbf{term} \ \ Semantics.matches \\ \textbf{term} \ \ Matching-Ternary.matches \end{array}$

The two matching semantics are related. However, due to the ternary logic, we cannot directly translate one to the other. The problem are MatchNot expressions which evaluate to TernaryUnknown because MatchNot TernaryUnknown and TernaryUnknown are semantically equal!

lemma $\exists m \ \beta \ \alpha \ a.$ Matching-Ternary.matches $(\beta, \ \alpha) \ m \ a \ p \neq$ Semantics.matches $(\lambda \ atm \ p. \ case \ \beta \ atm \ p \ of \ TernaryTrue \Rightarrow True \ | \ TernaryFalse$ $\Rightarrow False \ | \ TernaryUnknown \Rightarrow \alpha \ a \ p) \ m \ p$ apply(rule-tac $x=MatchNot \ (Match \ X) \ in \ exI)$ — any Xapply (simp split: ternaryvalue.split ternaryvalue.split-asm add: matches-case-ternaryvalue-tuple bunch-of-lemmata-about-matches)
by fast

the the in the next definition is always defined

lemma $\forall m \in \{m. \ approx \ m \ p \neq TernaryUnknown\}. \ ternary-to-bool (approx m \ p) \neq None$ **by**(simp add: ternary-to-bool-None)

The Boolean and the ternary matcher agree (where the ternary matcher is defined)

definition matcher-agree-on-exact-matches :: ('a, 'p) matcher \Rightarrow $('a \Rightarrow 'p \Rightarrow ternaryvalue) \Rightarrow bool$ where

matcher-agree-on-exact-matches exact approx $\equiv \forall \ p \ m.$ approx $m \ p \neq TernaryUn-known \longrightarrow exact m \ p = the \ (ternary-to-bool \ (approx \ m \ p))$

 $\mathbf{fun} \ \mathit{normalized-match} :: \ 'a \ \mathit{match-expr} \ \Rightarrow \ \mathit{bool} \ \mathbf{where}$

```
normalized-match MatchAny = True \mid normalized-match (Match -) = True \mid normalized-match (MatchNot (Match -)) = True \mid normalized-match (MatchAnd m1 m2) = ((normalized-match m1) \land (normalized-match m2)) \mid normalized-match m2 \rightarrow False
```

Essentially, normalized-match checks for a negation normal form: Only AND is at toplevel, negation only occurs in front of literals. Since 'a match-expr does not support OR, the result is in conjunction normal form. Applying normalize-match, the reuslt is a list. Essentially, this is the disjunctive normal form.

lemma normalized-match-normalize-match: $\forall m' \in set (normalize-match m)$. normalized-match m'

by (metis (poly-guards-query) nt-match-list-matches nt-match-list-simp)
Test if a disc is in the match expression. For example, it call tell whether
there are some matches for Src ip.
fun has\text{-}disc :: ('a \Rightarrow bool) \Rightarrow 'a \ match\text{-}expr \Rightarrow bool \ \mathbf{where}
  has\text{-}disc - MatchAny = False |
  has\text{-}disc\ disc\ (Match\ a) = disc\ a
  has-disc disc (MatchNot \ m) = has-disc disc m \mid
  has\text{-}disc\ disc\ (MatchAnd\ m1\ m2) = (has\text{-}disc\ disc\ m1\ \lor\ has\text{-}disc\ disc\ m2)
```

The following function takes a tuple of functions $(('a \Rightarrow bool) \times ('a \Rightarrow 'b))$ and a 'a match-expr. The passed function tuple must be the discriminator and selector of the datatype package. primitive-extractor filters the 'a match-expr and returns a tuple. The first element of the returned tuple is the filtered primitive matches, the second element is the remaining match expression.

It requires a normalized-match.

```
fun primitive-extractor :: (('a \Rightarrow bool) \times ('a \Rightarrow 'b)) \Rightarrow 'a \ match-expr \Rightarrow ('b \ negation-type \ list \times 'a \ match-expr) where
```

```
\begin{array}{l} primitive\text{-}extractor - MatchAny = ([], MatchAny) \mid \\ primitive\text{-}extractor (disc,sel) (Match a) = (if disc a then ([Pos (sel a)], MatchAny) \\ else ([], Match a)) \mid \\ primitive\text{-}extractor (disc,sel) (MatchNot (Match a)) = (if disc a then ([Neg (sel a)], MatchAny) \\ else ([], MatchNot (Match a))) \mid \\ primitive\text{-}extractor C (MatchAnd ms1 ms2) = (\\ let (a1', ms1') = primitive\text{-}extractor C ms1; \\ (a2', ms2') = primitive\text{-}extractor C ms2 \\ in (a1'@a2', MatchAnd ms1' ms2')) \end{array}
```

The first part returned by primitive-extractor, here as: A list of primitive match expressions. For example, let m = MatchAnd (Src ip1) (Dst ip2) then, using the src (disc, sel), the result is [ip1]. Note that Src is stripped from the result.

The second part, here ms is the match expression which was not extracted. Together, the first and second part match iff m matches.

18 Executable Packet Set Representation

Recall: alist-and transforms 'a negation-type list \Rightarrow 'a match-expr and uses conjunction as connective.

```
Symbolic (executable) representation. inner is \land, outer is \lor
```

 $\label{eq:datatype-new} \textbf{ datatype-new 'a packet-set} = PacketSet \ (packet-set-repr: (('a negation-type \times action negation-type) \ list) \ list)$

Essentially, the 'a list list structure represents a DNF. See Negation_Type_DNF.thy for a pure Boolean version (without matching).

```
definition to-packet-set :: action \Rightarrow 'a \ match-expr \Rightarrow 'a \ packet-set \ \mathbf{where} to-packet-set a \ m = PacketSet \ (map \ (map \ (\lambda m'. \ (m',Pos \ a)) \ o \ to-negation-type-nnf) \ (normalize-match \ m))
```

```
fun get-action :: action negation-type \Rightarrow action where get-action (Pos a) = a | get-action (Neg a) = a 

fun get-action-sign :: action negation-type \Rightarrow (bool \Rightarrow bool) where get-action-sign (Pos -) = id |
```

get-action-sign $(Neg -) = (\lambda m. \neg m)$

```
We collect all entries of the outer list. For the inner list, we request that a
packet matches all the entries. A negated action means that the expression
must not match. Recall: matches \gamma (MatchNot m) a p \neq (\neg matches \gamma m)
a p), due to TernaryUnknown
